Part 5:

A. Power on all routers and run Wireshark on R1. Apply a filter for OSPF, and look at the Hello Packets. How frequently are these packets sent, and why must they be sent periodically?

No.	Time	Source	Destination	Protocol	Length	Info
1566...	62840.134102...	10.20.1.42	224.0.0.5	OSPF	82	Hello Packet

1571...	62940.618662...	10.20.1.81	224.0.0.5	OSPF	82	Hello Packet

Every ten seconds, hello packets are sent out. In the Open Shortest Path First communications protocol, the HELLO packet is a particular data packet (message) that is sent out on a regular basis by a router to create and validate network adjacency connections with other routers. Routers in an OSPF network establish and maintain neighbor connections with other routers in the same OSPF region by sending out OSPF Hello packets on a regular basis. These hello packets perform a number of crucial tasks, such as identifying nearby neighbors, exchanging certain information, and confirming bidirectional connectivity.

B. Continue running Wireshark and turn off R4. You should now see new OSPF packet types captured on R1. Explain why Hello, Link State Update and Link State Acknowledgements use the same Destination IP address.

NetworkMiner capture showing OSPF traffic on interface *eth1. The capture file is named 'ospf'. The table lists 1490 packets, mostly OSPF Hello packets, with one LS Update packet highlighted.

No.	Time	Source	Destination	Protocol	Length	Info

Packet details for frame 1202:

- Frame 1202: 82 bytes on wire (656 bits), 82 bytes captured (656 bits) on interface 0
- Ethernet II, Src: 00:00:00_00:00:03 (00:00:00:00:00:03), Dst: IPv4mcast_05 (01:00:5e:00:00:05)
- Internet Protocol Version 4, Src: 10.10.10.2, Dst: 224.0.0.5
- Open Shortest Path First

In an OSPF network, when you disable router R4, R1 will recognize the modification in the network topology and reply with different kinds of OSPF packets. You will probably see additional OSPF packet types in this situation, such as Hello, Link State Update, and Link State Acknowledgment. Since all of these packets are intended for the AllSPFRouters multicast address, they will all utilize the same Destination IP address. This multicast address (224.0.0.5) is where OSPF routers transmit different kinds of OSPF packets for a wide range of purposes. Critical information about changes to the network topology and other important information is securely transmitted to all routers inside the OSPF region by utilizing the same multicast destination address for Hello, LSU, and LSAck packets. By doing this, the OSPF routing database's convergence and consistency across all local routers are maintained.

C. Based on the above steps, explain why we do not see DB Descriptions and LS Requests on R1. Is there a situation in which we get all OSPF packet types on R1?

Usually, we do not see OSPF Link State Request (LS Request) and Database Description (DBD) packets obtained on a router such as R1 during a routine OSPF operation. This is because, during the OSPF neighbor establishment and synchronization phase, there is a specific procedure that takes place between OSPF neighbors that involves the exchange of DBD and LS Request packets. In general, OSPF routers that are in the process of becoming neighbors or that need to synchronize their link-state databases exchange DBD and LS Request packets as part of the OSPF neighbor establishment and synchronization process. These packets are unique to the

OSPF routers taking part in this synchronization and are not frequently observed on any network.
